

TWO SPECIES ADDED TO THE LIST OF
BALINESE ODONATA, INDONESIA

In 1953, M.A. LIEFTINCK (*Verh. naturf. Ges. Basel* 64: 118-128) published a checklist of the Odonata from the Lesser Sunda Islands of Bali and Lombok. In 1994, I have given a list, adding 5 species (*Notul. odonatol.* 4: 60-62). J. RUDDEK (1998, *Notul. odonatol.* 5: 11) reported *Euphaea lara lombockensis* McL., *Macrodiplax cora* (Br.), *Orthetrum glaucum* (Br.) and *Tramea e. eurybia* (Sel.) from Lombok, but the latter three species were only sighted and photographed, while the first species is now in the genus *Allophaea*. I would maintain 31 as the number of the species known from Lombok – until the latter three species will have been actually collected there and identified under the microscope.

Here, two more species are brought on record from Bali:

- (1) *Agriocnemis pygmaea* (Ramb.). – On 8-II-1999, the enthusiastic nature lover and photographer, Mr Ben Storm van 's Graven-sande (Oosterhout) was able to collect 3 ♂ and 1 ♀ of this very small, fragile and feebly flying zygopteran in a grassfield nearby the restaurant, "El Paradiso", in Kuta. He has kindly given me the specimens.
- (2) *Tholymis tillarga* (Fabr.). – On 21-II-2000, a ♀ was collected by myself, at twilight, at an artificial pond in the garden of "Hotel Melasti Beach Bungalows", also in Kuta, and situated next to the above mentioned resto-rant.

These records bring the number of species known from Bali up to 45.

All specimens taken in Bali are deposited in the Leiden Museum.

My thanks are due to Mr JAN VAN TOL (National Museum of Natural History, Leiden), who kindly identified the Balinese *A. pygmaea* specimens.
